ABSTRACT

The paper considers three methods for eliminating the zero lower bound on nominal interest rates and thus for restoring symmetry to the domain over which the Central Bank can vary its official policy rate. They are: (1) abolishing currency (which would also be a useful crime-fighting measure); (2) paying negative interest on currency by taxing currency; and (3) decoupling the numéraire from the currency/medium of exchange/means of payment and introducing an exchange rate between the numéraire and the currency; this exchange rate can be set over time to achieve a forward discount (expected depreciation) of the currency vis-à-vis the numéraire when the nominal interest rate in terms of the numéraire is set at a negative level for monetary policy purposes.

1. Introduction

There is a notable asymmetry in the design and implementation of monetary policy: nominal interest rates cannot be negative. During boom times, when the economy is overheating and inflation threatens to rise to undesirable levels, the Central Bank can raise the official policy rate (a short, risk-free nominal interest rate, typically the target for the overnight interbank rate) to any level it deems necessary. During economic downturns, when excess capacity rises and deflation threatens, the official policy rate can be cut no further than zero. If a further stimulus is desired, unconventional monetary policy, such as quantitative easing, credit easing or enhanced credit support must be resorted to.

The zero lower bound is not just of academic interest. At the time of writing (November 2009), in Japan and the U.S., the official policy rates are effectively at their zero floors. In the UK, Bank Rate is 0.50 percent, which the Bank of England regards, for technical operational reasons, as its effective zero lower bound. In the Euro Area, the official policy rate still stands at 1.00 percent, but the rate banks get on their reserves with the Central Bank is only 0.25 percent.

A number of economists have suggested that, using calculations based on variations of the Taylor rule (a rule that makes the official policy rate an increasing function of the output gap and of the excess of actual or expected inflation over target inflation) and ignoring the zero lower bound, the official policy rate in the U.S. early in 2009 should have been as low as minus 5 percent or even minus 7.5 percent. The minus 7.5 percent figure was suggested in March 2009 as a level of the Federal Funds target rate that could be required by the end of 2009, by Laurence Meyer, a former Fed Board member, now vice chairman of Macroeconomic Advisers, in a note to clients. The minus five percent figure was widely reported in April 2009, as the product of internal analysis prepared by Fed staff for the Federal Reserve’s last policy meeting (see e.g., Financial Times, 2009; Taylor, 2009b).

Whatever the merits of the Taylor rule and the specific calculations, there is a strong case that the zero lower bound has indeed, during the current downturn, been a binding constraint on Central Bank interest rate setting.

The zero lower bound on the short risk-free nominal interest rate on non-monetary financial instruments derives from the existence of a risk-free nominal instrument that carries a zero interest rate. The instrument in question, currency, has other attractive properties such as legal tender status that are not shared by Treasury Bills and other nominally denominated non-monetary stores of value. Currency is also, for most practical purposes, perfectly liquid. Therefore, a Treasury Bill or similar risk-free instrument with a negative nominal interest rate would be dominated as a store of value by currency. There would be a simple pure arbitrage opportunity for anyone able to borrow at a negative nominal interest rate and invest in zero nominal interest rate currency.

The reason no interest, at a positive or at a negative rate, is paid on currency is that it is costly and administratively awkward and intrusive to do so. All financial instruments can be divided into two categories: bearer instruments and registered instruments. Registered instruments are instruments wherein the identity of the owner is recorded in some central register or publicly accessible database. The issuer of the security therefore knows the identity of the holder. Common stock is an example. So are bank accounts, including commercial bank accounts held with the Central Bank. Negative interest rates on bank balances could be as easily implemented as positive interest rates—both are just entries in an electronic ledger. Negative dividends are not technically difficult (it would amount to a compulsory cash call on the shareholders) although it may not be legally permissible in most jurisdictions. In addition, since equity has a variable market value, nominal rates of return can be negative, when dividends and capital gains are considered together. The same holds for fixed-interest nominal debt instruments.

Bearer instruments have anonymous owners: the issuer (borrower) does not know the identity of the owner (creditor, holder or bearer). This makes it difficult to pay even positive interest rates: the owner/bearer could present the same instrument repeatedly to the owner for payment of interest due only once. The solution is to ‘mark’ the instrument itself, so it can be identified as current on interest. Historically, this was done by ‘clipping coupons’ off fixed interest bonds or by stamping the bond document. Paying negative interest on bearer instrument is even harder, because the issuer has to induce the holder to come forward to pay to the issuer the interest due. The holder is anonymous. Why would he volunteer to reveal himself to the issuer?
Currency being a bearer instrument is a necessary but not a sufficient condition for the payment of interest on currency, positive or negative, to be difficult. Many of the most common bonds are, after all, bearer instruments. Currency, however, is a negotiable bearer bond, and one that is transferable without endorsement. A financial instrument is negotiable if it is transferable from one party to another by being delivered (with or without endorsement) so that the title passes to the transferee. Thus, not only does the issuer not know the identity of the holder of a negotiable bearer bond, that holder can change easily and with little cost. It is therefore very difficult to keep track of who is the owner of a specific negotiable bearer bond. The solution again is that if you cannot identify the owner, you identify/mark the individual instruments themselves as current on interest due.

Operationally, this marking of instruments can be achieved by putting an expiration date on the instrument. The legal definition of the instrument could stipulate that, unless interest due by the bearer to the issuer is paid before the expiration date and the instrument is marked as current on interest due, the instrument represents no further claim on the issuer. During the 1930s, there were many experiments, in continental Europe, Canada and the U.S., with sub-national stamp scrip money.

The problem in applying this to government fiat currency is that currency has no expiration date. As a financial instrument, it is like a zero coupon perpetuity or consol—a promise to pay nothing forever. While private or local government IOUs may lose their value if they are not at some point redeemable (at least in principle) into legal tender, currency is already legal tender. It is also irredeemable: it does not represent a claim on the issuer for anything other than the same amount of itself. So incentives have to be created to induce private holders of currency to reveal their ownership of currency, come forward and pay any negative interest due. This would require the costly verification of the status of currency notes and the imposition of fines and other punishments on the holders if interest is overdue.

No government has, as yet, had the stomach for that.

This paper considers three methods for removing the zero lower bound on nominal interest rates. Each follows a quite different route, although the end result is the same. The first, abolishing currency, ensures that all money (means of payment/media of exchange) consists of registered instruments

---

2 The vast majority of international bonds, historically called Eurobonds, are bearer. Bearer bonds can take two main forms. First, the traditional definitive style, where the bonds literally are individual pieces of security—printed paper in denominations of, say, $10,000, which individual holders bring in to paying agents so as to receive payment of interest and principal. Second, global bonds, which are technically bearer instruments but consist of a single piece of paper representing the entire issue (and so worth hundreds of millions or even billions of dollars). In practice, the terms of the global bond say that only Euroclear (the settlement system based in Brussels) or Cedelbank (the settlement system based in Luxembourg) are entitled to the proceeds of the global bond, and that Euroclear and Cedelbank will in turn divide the proceeds up amongst the end-investors whose details are stored in their electronic records. Thus the global bond is not an instrument which in practice can be passed from one owner to another, even though it is technically bearer. Effectively the bonds are dematerialised. Bearer bonds are legal and quite common in the UK. While the bearer debenture went out of use, replaced by the non-negotiable debenture or debenture stock, transferable (in the same way as common stocks) by entry in the company’s register, a number of new negotiable investment securities have evolved. They include the modern bearer bond, the negotiable certificate of deposit, and the floating rate note. A limited number of giltls have also been issued with a bearer option. Before July 1983, municipal securities in the U.S. were issued for the most part in certificate form with coupons attached. Some of these so-called old-style bearer bonds are still available in the marketplace. The issuer has no record of who owns these bonds. The owner clips the coupons and collects the interest from the issuer’s paying agent. Transferring the bonds requires physical delivery and payment. Bearer bonds issued by municipal authorities were made illegal in the U.S. in 1982.

3 Key elements of negotiability include the following: (1) transfer by physical delivery; (2) transfer confers on its holder unchallengeable title and (3) a negotiable instrument benefits from a number of evidential and procedural advantages in the event of a court action.

4 An endorsement is a signature on a negotiable instrument indicating a person’s intent to become a party to the instrument.

5 From the Federal Reserve Bank of Cleveland (2008), I cite the following: “Stamp scrip, sometimes called coupon scrip, arose in several communities. It was denominated in dollars, in denominations from 25 cents to $5, with $1 denominations most common. Stamp scrip often became redeemable by the issuer in official U.S. dollars after one year. What made stamp scrip unique among scrip schemes was a series of boxes on the reverse side of the note. Stamp scrip took two basic forms—and undated (often called “transaction stamp scrip”). Typically, 52 boxes appeared on the back of dated stamp scrip, one for each week of the year. In order to spend the dated scrip, the stamps on the back had to be current. Each week, a two-cent stamp needed to be purchased from the issuer and affixed over the corresponding week’s box on the back of the scrip. Over the coming week, the scrip could be spent freely within the community. Whoever was caught holding the scrip at week’s end was required to attach a new stamp before spending the scrip. In this scheme, money became a hot potato, with individuals passing it quickly to avoid having to pay for the next stamp.”
on which the payment of positive or negative interest is trivially easy. The second, taxing currency, is a means of paying negative interest on currency, using what amounts to stamp scrip methods, even though more high-tech ways than physically stamping bank notes are now available as means of identifying currency notes as current on interest due. The third method decouples the numéraire function of currency from its means of payment/medium of exchange function and introduces a variable exchange rate between a unit of the one-period safe non-monetary security denominated in terms of the numéraire and the currency/means of payment. That exchange rate can either be set by the government or be market-determined. This permits the nominal interest rate in terms of the numéraire to be negative, even though the nominal interest rate in terms of the currency is subject to the zero lower bound.

The literature on negative nominal interest rates is limited. There is the notable work by Silvio Gesell (1916) and the Great Depression-era writings of Robert Eisler (1932) and Irving Fisher (1933). In the ‘modern era’, only Robert Hall has repeatedly addressed issues close to the ones considered in this paper (Hall, 1983, 1997, 2002; Hall & Woodward, 2009). The issue of the zero lower bound became of interest again since about 1996, following the Japanese zero interest rate policy and experiment with quantitative easing, and because of the low nominal interest rates encountered in much of Europe and the U.S. following the bursting of the tech bubble at the end of 2000. Examples are Goodfriend (2000), Buiter and Panigirtzoglou (2001, 2003), Buiter (2004, 2007a), Buiter and Sibert (2007), Davies (2004) and Fukao (2005). The experience since late 2008 of having most leading Central Banks at or near the zero lower bound has resurrected the policy debate, mainly in the blogosphere, in parliamentary or congressional evidence or in speeches since 2008 (Buiter, 2009a,b,c; Mankiw, 2009; Taylor, 2009a,b).

Section 2 develops a simple formal model which is used, in Section 3, to present the three methods for removing the zero lower bound. Section 4, prompted by discussions with Fabrizio Zilibotti, offers a number of re-interpretations and extensions of the third method—unbundling numéraire and currency. Section 5 points out that the model does not support a liquidity trap equilibrium (short nominal interest rates at their lower bounds for all maturities) if the authorities pursue even the mildest form of quantitative easing.

2. A simple model of the euro currency economy

I will formally present the main ideas about removing the lower bound on the short-term risk-free nominal interest rate using a simple model of a closed endowment economy with a representative infinite-lived household consumer-worker-portfolio manager and a government sector consisting of a consolidated Central Bank and Treasury. For simplicity, and because none of the results of this paper depend on it, I assume that there exists a complete set of time- and state-contingent markets. Price setting follows a variant of the New-Keynesian Calvo-Woodford approach (Calvo, 1983; Woodford, 2003).

2.1. The private sector in the euro-currency economy

In the benchmark economy, the currency is the euro. It is also the numéraire. The competitive representative household receives an endowment $y_t > 0$ of a single perishable commodity (potential labour time) each period, $t = 0, 1, 2, \ldots$, which it takes as given. It can either consume the endowment or sell it to other consumers or to the government. The household maximizes lifetime expected utility, as defined in Eq. (1).

The lifetime utility functional is defined over an infinite horizon, is time-additive and has a constant psychological discount factor $\beta$. The period utility function is increasing in consumption $c_t \geq 0$ and real euro base money balances $m_t \geq 0$, and strictly concave. The results of the paper are not affected if the ‘money-in-the-direct-utility-function approach’ were to be replaced by a ‘cash-in-advance’ approach, a ‘shopping-time’ approach or a ‘money-in-the-production-function’ approach.

---

6 In a longer version of the paper, I establish a map between the two short nominal interest rates of the formal model and the much larger set of short nominal interest rates encountered in the real world of Central Banking.
For expositional and notational simplicity, the period utility function is assumed to be additively separable in consumption and the real euro monetary base. Each of the sub-utility functions is assumed to be iso-elastic. The conditional expectation operator at time $t$ is denoted $E_t$, the nominal stock of base money at the end of period $t$ is $M_t$, $P_t$ is the period-$t$ general price level and $m_t = M_t/P_t$. Note that $M_t$ is the stock of euro base money and that $P_t$ is the euro price level in period $t$. Until Section 3 the formal model treats base money as a homogeneous instrument with an exogenous single-period own rate of interest, $i_M$, rather than decomposing it into currency, $N$, and reserves with the Central Bank, $D$, each with its own, possibly distinct, interest rate.

\[
U_0 = E_0 \sum_{t=0}^\infty \beta^t \left[ \frac{1}{1-\gamma} c_t^{1-\gamma} + \frac{1-\gamma}{1-\gamma} \ln m_t^{1-\gamma} \right]
\]

\[0 < \beta < 1; \eta, \gamma > 0\]  

The household’s optimisation programme is subject to its period budget identity (2), its solvency constraint (3) and initial conditions for its financial assets (4). The risk-free one-period nominal interest rate on non-monetary assets in period $t$ is $i_{t+1,t}$, the period $t$ one-period risk-free nominal interest rate on base money is $i_M^{t+1,t}$, $\tau_t$ is real lump-sum taxes paid in period $t$, $I_{t+1,t}$ is the one-period stochastic nominal discount factor in period $t$, $W_t$ is the value of the portfolio of financial assets (including money) in period $t$, and $A_t$ is the value in period $t$ of the portfolio of non-monetary financial assets carried over from period $t-1$, including interest or other income paid.

\[
E_t \left( I_{t+1,t} W_{t+1} \right) = W_t + P_t(y_t - c_t - \tau_t) - \left( \frac{i_{t+1,t} - i_M^{t+1,t}}{1 + i_{t+1,t}} \right) M_t
\]

\[
\lim_{k \to \infty} E_t I_{k+1,t} W_k \geq 0.
\]

\[M_{t-1} = \bar{M}_{t-1} > 0\]

\[A_0 = \bar{A}_0\]

Here $I_{t_1,t_0}$ is the nominal stochastic discount factor between periods $t_1$ and $t_0$ with:

\[I_{t_1,t_0} = \prod_{k=t_0+1}^{t_1} I_{k,k-1}; \quad t_1 > t_0 \equiv 1 \quad t_1 = t_0.\]

The risk-free one-period nominal rate of interest is defined as follows:

\[
\frac{1}{1 + i_{t+1,t}} = E_t I_{t+1,t}
\]

By definition:

\[W_t = A_t + (1 + i_{t,t-1}^M)M_{t-1}\]

The period budget identity and the solvency constraint imply the household’s intertemporal budget constraint:

\[W_t = P_t(c_t + \tau_t - y_t) + \left( \frac{i_{t+1,t} - i_M^{t+1,t}}{1 + i_{t+1,t}} \right) M_t\]

\[+ E_t \sum_{j=1}^\infty I_{t+j,t} \left( P_{t+j}(c_{t+j} + \tau_{t+j} - y_{t+j}) + \left( \frac{i_{t+j+1,t+j} - i_M^{t+j+1,t+j}}{1 + i_{t+j+1,t+j}} \right) M_{t+j} \right) + E_t \lim_{T \to \infty} I_{t+T,t} W_{t+T}\]
The inflation factor (1 plus the proportional rate of inflation) between periods \( t_1 \) and \( t_0 \) is denoted \( \Pi_{t_1, t_0} = P_{t_1} / P_{t_0} \), \( t_0, t_1 \geq -2 \) (9) and the real stochastic discount factor between periods \( t_1 \) and \( t_0 \) is denoted \( R_{t_1, t_0} = \Pi_{t_1, t_0} \). The one-period risk-free real interest rate, \( r_{t+1, t} \) is defined as:

\[
\frac{1}{1 + r_{t+1, t}} = E_t R_{t+1, t} \quad (10)
\]

For future reference, the multi-period real stochastic discount factors are defined recursively as follows:

\[
R_{t_1, t_0} = \prod_{k=t_0+1}^{t_1} R_{k, k-1} \quad t_1 > t_0
\]

\[
= 1 \quad t_1 = t_0. \quad (11)
\]

The optimality conditions of the household optimisation programme are the following (\( Cov_t \) denotes the conditional covariance at time \( t \)):

\[
c_t^{-\gamma} = \beta(1 + r_{t+1, t})E_t c_{t+1}^{-\gamma} \quad (12)
\]

\[
\frac{M_t}{P_t} = \left[ \eta \left( \frac{1 + i_{t+1, t}}{i_{t+1, t} - iM_{t+1, t}} \right) \right]^{1/\gamma} c_t. \quad (13)
\]

\[
\lim_{T \to \infty} E_t \left( \frac{\beta^T M_{t+T}}{c_{t+T}^{-\gamma} P_{t+T}} \right) = 0 \quad (14)
\]

\[
1 + r_{t+1, t} = \left( 1 + i_{t+1, t} \right) \left( E_t \Pi_{t+1, t}^{-1} + \frac{Cov_t(\Pi_{t+1, t}^{-1}, c_{t+1}^{-\gamma})}{E_t c_{t+1}^{-\gamma}} \right) \quad (15)
\]

\[
W_t = P_t (c_t + \tau_t - y_t) + \left( \frac{i_{t+1, t} - iM_{t+1, t}}{1 + i_{t+1, t}} \right) M_t + E_t \sum_{j=1}^{\infty} I_{t+j, t} \left( P_{t+j}(c_{t+j} + \tau_{t+j} - y_{t+j}) + \left( \frac{i_{t+j+1, t+j} - iM_{t+j+1, t+j}}{1 + i_{t+j+1, t+j}} \right) M_{t+j} \right) \quad (16)
\]

or equivalently

\[
E_t \lim_{T \to \infty} I_{t+T, t} W_{t+T} = 0
\]

The household solvency constraint (3) holds with equality. Eq. (12) is the Euler equation for consumption. The demand for real euro money balances is proportional to consumption and depends inversely on the pecuniary opportunity cost of holding money, \( i_{t+1, t} - iM_{t+1, t} \). Eq. (14) is the transversality condition governing the long-run behaviour of the stock of money balances (see Buiter & Sibert, 2007). It says that the value, across all states of nature, of the terminal stock of real money balances, evaluated at its appropriate present value shadow price, is zero. So either the stock of real money balances goes to zero or its shadow price goes to zero, or both. The state-contingent present value shadow price of terminal real money balances equals the terminal marginal utility of consumption discounted using the subjective discount factor. The risk-free real interest rate equals the risk-free nominal interest rate minus the expected inflation rate and the inflation risk premium (Eq. (15)).

Pricing behaviour is assumed to be governed by a New-Keynesian Phillips curve with both a backward-looking and forward-looking inflation component in the ‘augmentation term’; \( \bar{y}_t > 0 \) is
the exogenous level of capacity output or potential output in period \( t \).

\[
\Pi_{t,t-1} = \alpha^{-1} (y_t - \bar{y}_t) + (1 - \lambda) E_t \Pi_{t+1,t} + \lambda \Pi_{t-1,t-2}
\]

\( 1 \geq \lambda \geq 0; \alpha \geq 0 \) (17)

\[
P_{-2} = \tilde{P}_{-2}
\]

\[
\Pi_{-1,-2} = \tilde{\Pi}_{-1,-2}
\]

Perfect price flexibility is the special case of (17) where \( \alpha = 0 \), in which case it becomes \( y_t = \bar{y}_t \) for all \( t \geq 0 \).

2.2. The government in the euro currency economy

The government in what follows is the consolidated general government and Central Bank. It spends on real goods and services, \( g_t \) with \( 0 \leq g_t \leq \bar{y}_t \), raises real revenues \( r_t \) and finances its financial deficit by issuing base euro money, \( M_t \) or safe, euro-denominated one-period government debt, \( B_t \).

The government’s period budget identity is

\[
M_t + B_t = (1 + iM_{t,t-1})M_{t-1} + (1 + it_{t,t-1})B_{t-1} + Pt (g_t - t_t)
\]

This can be re-written as

\[
(1 + iM_{t,t-1})M_{t-1} + (1 + it_{t,t-1})B_{t-1} = Pt (r_t - g_t) + M_t + E_t iM_{t+1,t} - \frac{M_t}{1 + it_{t+1,t}}
\]

Solving this forward recursively yields:

\[
(1 + iM_{t,t-1})M_{t-1} + (1 + it_{t,t-1})B_{t-1} = Pt (r_t - g_t) + \frac{M_t}{1 + it_{t+1,t}}
\]

\[+E_t \sum_{j=1}^{\infty} P_{t+j}(\bar{r}_{t+j} - g_{t+j}) \left( \frac{\bar{t}_{t+j+1,t+j} - \bar{r}_{t+j+1,t+j}}{1 + \bar{t}_{t+j+1,t+j}} \right) M_{t+j}
\]

\[+E_t \lim_{T \to \infty} I_{t+T+1,t} \left( 1 + iM_{t+T+1,t+T} \right) M_{t+T} + (1 + it_{t+T+1,t+T})B_{t+T}
\]

or, equivalently

\[
(1 + iM_{t,t-1})M_{t-1} = Pt (r_t - g_t) + M_t - (1 + iM_{t,t-1})M_{t-1}
\]

\[+E_t \sum_{j=1}^{\infty} P_{t+j}(\bar{r}_{t+j} - g_{t+j}) + M_{t+j} - (1 + iM_{t+j,t+j-1})M_{t+j-1}
\]

\[+E_t \lim_{T \to \infty} I_{t+T+1,t} (1 + it_{t+T+1,t+T})B_{t+T}
\]

The equivalence of the two intertemporal government budget identities in (20) can also be expressed through what I have called the intertemporal seigniorage identity, linking two common concepts of ‘seigniorage’—the revenue obtained by the state from the issuance of base money (Buiter, 2007b). The first is the present discounted value of current and future base money issuance; the second is the present discounted value of current and future interest payments foregone due to the state’s
issuance of base money rather than risk-free non-monetary assets:

\[
E_t \sum_{j=1}^{\infty} i_{t+j,t} \left( M_{t+j} - (1 + i^M_{t+j,t+j-1})M_{t+j-1} \right) = E_t \sum_{j=0}^{\infty} i_{t+j,t} \left( \frac{I_{t+j+1,t+j} - i^M_{t+j+1,t+j}}{1 + i^M_{t+j+1,t+j}} \right) M_{t+j}
\]

(21)

\[
E_t \lim_{T \to \infty} I_{t+T+1,t} (1 + i^M_{t+T+1,t+T})M_{t+T} = -(1 + i^M_{t,T-1})M_{t-1}
\]

The solvency constraint for the government is that the present discounted value of its terminal non-monetary liabilities be non-positive:

\[
E_t \lim_{T \to \infty} I_{t+T+1,t} (1 + i^M_{t+T+1,t+T})B_{t+T} \leq 0
\]

(22)

Note the contrast between (22) and (3). Anticipating the asset market equilibrium condition, it is clear that, in equilibrium,

\[ A_t = (1 + i_{t-1})B_{t-1} \]

Since \( W_t = A_t + (1 + i^M_{t-1})M_{t-1} = (1 + i_{t-1})B_{t-1} + (1 + i^M_{t-1})M_{t-1} \), the household solvency constraint (3) can in equilibrium be written as:

\[
E_t \lim_{T \to \infty} I_{t+T+1,t} \left( (1 + i_{t+T+1,t+T})B_{t+T} + (1 + i^M_{t+T+1,t+T})M_{t+T} \right) \geq 0
\]

(23)

Comparing (22) and (23), households treat their holdings of government base money as an asset, even in the long run, while the government recognises that fiat base money is irredeemable: it does not represent a claim on the issuer for anything other than the same amount of itself (e.g., two five euro notes for one ten euro note). As it is irredeemable it does not belong in the government’s solvency constraint. This, I believe, is the correct mathematical expression of the well-known idea in monetary economics that fiat money represents an asset to the owner, but not a liability to the issuer (see Buiter, 2003).

Government spending, \( g_t \), is exogenous, as is the nominal interest rate on euro base money, \( i^M_{t-1,t-1} \). The short risk-free nominal interest rate on the euro-denominated bond is governed by a simplified Taylor rule, where the short rate responds more than one-for-one to the expected rate of inflation, as long as the lower bound constraint, that the short risk-free nominal interest rate on bonds cannot be lower than the short risk-free nominal interest rate on base money, is not binding. If the Taylor rule were to cause the constraint to bind, the short nominal interest rate on bonds is set equal to the nominal interest rate on base money; \( \hat{\Pi} = 1 \) is the exogenous target inflation rate, assumed constant.

\[
1 + i_{t+1,t} = \beta^{-1} \hat{\Pi} + \phi(E_t \Pi_{t+1,t} - \hat{\Pi}), \text{ if } \beta^{-1} \hat{\Pi} + \phi(E_t \Pi_{t+1,t} - \hat{\Pi}) > 1 + i^M_{t+1,t}
\]

\[
= 1 + i^M_{t+1,t}, \text{ if } \beta^{-1} \hat{\Pi} + \phi(E_t \Pi_{t+1,t} - \hat{\Pi}) \leq 1 + i^M_{t+1,t}
\]

(24)

\[ \phi > 1 \]

If the lower bound constraint binds, the government engages in quantitative easing (QE), according to (25):

\[
\text{If } i_{t+1,t} = i^M_{t+1,t} \text{ then } M_{t+1} = (1 + \mu_{t+1,t})M_t
\]

(25)

The proportional growth rate of base money under QE, \( \mu_{t+1,t} \), is assumed to be exogenous subject to \( \mu_{t+1,t} > -1 \). When the lower bound constraint \( i \geq i^M \) binds, the nominal stock of money becomes a choice variable of the government—a policy instrument. This is true even when the authorities ‘monetary’ policy rule when the lower bound constraint does not bind is a rule for the short nominal interest rate, like the simplified Taylor rule of this model. The policy rule governing the nominal stock of base money under QE could take any form. The exogenous sequence of base money growth rates assumed here is just for expositional simplicity. The second half of the interest rate rule in (24),

\[
1 + i_{t+1} = 1 + i^M_{t+1,t}, \text{ if } \beta^{-1} \hat{\Pi} + \phi(E_t \Pi_{t+1,t} - \hat{\Pi}) \leq 1 + i^M_{t+1,t}
\]
is not redundant. In principle, should the Taylor rule produce a nominal interest rate value at or below the interest rate on currency, the authorities could set the actual interest rate at any level equal to or greater than the interest rate on currency.

When the lower bound constraint does not bind, the nominal stock of base money, $M_t$, is endogenously determined from the money demand function (13). The stock of one-period non-monetary government debt, $B_t$, and real lump-sum taxes, $\tau_t$, are only constrained by the requirement that the government’s solvency constraint (22) be satisfied. There are many possible tax rules or borrowing rules satisfying this, including, trivially, the rule that the stock of non-monetary public debt is always equal to zero, given in (26):

$$\tau_t = g_t - \frac{1}{P_t} \left( M_t - (1 + i_{t,t-1}^M)M_{t-1} - (1 + i_{t,t-1})B_{t-1} \right) \quad t \geq 0$$

(26)

### 2.3. Equilibrium in the euro currency economy

Goods market equilibrium and asset market equilibrium are given by (27) and (28) respectively, for $t \geq 0$.

$$y_t = c_t + g_t$$

(27)

$$A_t = (1 + i_{t,t-1})B_{t-1}$$

(28)

The full set of equilibrium conditions consists of eleven Eqs. ((7), (9), (12), (13), (15), (17), (19), (24), (25), (27) and (28)) which hold for $t \geq 0$, four initial conditions

$$M_{-1} = \bar{M}_{-1} > 0$$

(29)

$$B_{-1} = \bar{B}_{-1}$$

(30)

$$\Pi_{-1,-2} = \bar{\Pi}_{-1,-2} > 0$$

(31)

$$P_{-2} = \bar{P}_{-2} > 0$$

(32)

the transversality condition (14), and the solvency constraint for the household sector

$$E_t \lim_{T \to \infty} I_{t+T,T}W_{t+T} = 0$$

(33)

They determine, for $t \geq 0$, and for given state-contingent sequences of the exogenous variables $\{g_t, i_{t,t-1}^M, \mu_{t,t-1}, \bar{y}_t; \ t \geq 0\}$ the equilibrium values of $\{c_t, r_{t+1,t}, i_{t+1,t}, y_t, M_t, B_t, A_t, W_t, \tau_t, P_t, \Pi_{t,t-1}; \ t \geq 0\}$.7

### 2.4. The deterministic steady state in the euro currency economy

It will be useful for future reference, to consider the steady state of the deterministic special case of the model when all exogenous variables are constant. This is also the stationary (fundamental) equilibrium of the flexible price level version ($\alpha^{-1} = 0$) of the model of the previous three subsections.

$$1 + r = \beta^{-1}$$

(34)

$$m = \frac{M_t}{P_t} = \left[ \eta \left( \frac{1 + i_{t,t-1}^M}{1 - \bar{M}} \right) \right]^{1/\gamma} (\bar{y} - g)$$

(35)

$$\Pi = \frac{1 + i}{1 + r}$$

(36)

---

7 Strictly speaking, I should here also provide the equations determining the infinite-horizon nominal stochastic discount factors $\lim_{T \to \infty} I_{t+T,T}$, which discount terminal household financial wealth in (33). For reasons of space this is omitted.
\[
\lim_{t \to \infty} \frac{\beta^T}{(\bar{y} - g)_{\gamma}^T} \frac{M_t}{P_t} = \lim_{t \to \infty} \left( \frac{\beta^T}{(\bar{y} - g)_{\gamma}^T} \frac{M_0(1 + \mu)^T}{IT^T P_0} \right) = \lim_{t \to \infty} \left( \frac{(\bar{y} - g)^{-\gamma} M_0}{P_0} \left( \frac{1 + \mu}{1 + i} \right)^T \right) \tag{37}
\]

If \( \beta^{-1} > 1 + i^M \) then \( 1 + i = \beta^{-1} \bar{\alpha} \)

If \( \beta^{-1} \bar{\alpha} \leq 1 + i^M \) then \( i = i^M \)

\[ \tag{38} \]

If \( i = i^M \) then \( M_{t+1} = (1 + \mu)M_t \)

\[ \tag{39} \]

2.5. The lower bound can become a binding constraint in the euro currency economy

It is clear that the constraint \( i \geq i^M \) can bind in our model. From Eqs. (34)–(39), interpreted as the fundamental solution of the deterministic flexible price level special case when the exogenous variables are all constant, it can be verified by inspection that a sufficiently low target rate of inflation, \( \bar{\alpha} - 1 \), possibly assisted by a sufficiently low pure rate of time preference, \( \beta^{-1} - 1 \), can cause the lower bound constraint to bind. From Eq. (38), however, this would require, if the nominal interest rate on base money is zero, a negative target rate of inflation that is equal to or larger in absolute value than the pure rate of time preference. In the New-Keynesian variant of the model \( (\alpha > 0) \), there always exists a sufficiently large negative shock to \( g_t - \bar{y}_t \) to ensure that the lower bound constraint binds.

3. Overcoming the lower bound on nominal interest rates

I now consider the three methods for removing the lower bound on nominal interest rates referred to in the introduction: (1) abolishing currency, (2) paying negative interest on currency or taxing currency, and (3) separating the medium of exchange/means of payment function from the numéraire function.

3.1. Abolishing currency

Base money, \( M \), is the sum of currency, \( N \geq 0 \) and bank deposits held with the Central Bank, \( D \), that is, \( M = N + D \). The interest rate on currency, \( i^N \), is zero, because it is a negotiable bearer bond. The interest rate on commercial bank deposits with the Central Bank, \( i^D \) can be zero, positive or negative without significant administrative or enforcement costs, because these deposits are registered financial instruments. From a government and private sector financing perspective currency and deposits are perfect substitutes, but from the point of view of the provision of liquidity services, currency and deposits may not be perfect substitutes. One simple way to formalise this is by representing base money in the utility function as a constant-returns-to-scale CES function of \( N \) and \( D \), with elasticity of substitution \( \theta \) between currency and bank deposits as regards the provision of liquidity services. So \( m \) in the period utility function in Eq. (1) is no longer given by \( m = M/P \) but instead becomes:

\[
m = P^{-1} \Lambda \left( a N^{\theta-1} + (1 - a) D^{\theta-1} \right)^{\theta/\theta-1} \Lambda > 0; \quad 0 \leq a \leq 1, \theta \geq 0 \tag{40} \]

Abolishing currency would mean setting \( N_t = 0, t \geq 0 \), leaving only bank deposits with the Central Bank to provide the monetary base function. With positive or negative interest rates on bank deposits with the Central Bank feasible at trivial cost, the lower bound on the short, risk-free non-monetary nominal interest rate would be removed.

The expected welfare gain associated with the removal of the zero lower bound on currency, achieved through an enhanced capacity of the monetary authority to respond to shocks, would have

---

8 Without changing the argument in any meaningful way, we can permit negative values for \( D \) letting that stand for commercial bank borrowing from the Central Bank against high-grade collateral, say Treasury Bills.

9 The government’s period budget identity (19), for instance, becomes \( N_t + D_t + B_t = N_t(1 + i^D_{t-1})D_{t-1} + (1 + i^D_{t-1})B_t + P_t (g_t - \bar{y}_t) \).
to be balanced against the welfare consequences of the loss of currency. In our model, there would be no welfare impact from the loss of currency if currency and bank deposits were perfect substitutes as regards the provision of liquidity services \((\theta = +\infty)\). Even if currency and commercial bank deposits with the Central Bank are imperfect substitutes as regards the provision of liquidity services, the authorities can still achieve satiation with real liquidity services, even without currency, by setting \(i_{t+1}^M = i_{t+1}^D = i_{t+1}^C\), that is, by requiring the interest rate on commercial bank reserves with the Central Bank to track the short safe nominal rate on non-monetary securities (determined in our model by the simplified Taylor rule).

What would the real-world costs of abolishing currency (that is, government-issued fiat base money in the form of negotiable and freely transferable bearer securities with legal tender status)?

In advanced industrial countries, with well-developed financial markets and institutions, and with an ever-growing range of electronic payment and settlement vehicles, currency has effectively become a redundant medium of exchange and means of payment for legitimate, legal transactions (see e.g., Bolt, 2006). As regards legitimate transactions, they are only used for small retail payments. In countries with developed financial systems, the existence of checkable bank deposits, giro accounts at post offices, checkable money market accounts, charge cards, credit cards, debit cards, a wide range of private forms of e-money or digital cash cards, like the CashCard made by NETS or the EZ-link card, means that currency has become redundant as a means of payment for legitimate transactions in goods and services and as a store of value for legitimately acquired financial wealth, except for the poorest members of society.

Although hard evidence is, for obvious reasons, difficult to come by, there is a reasonable presumption that the majority of U.S. dollar and euro currency notes either are held abroad for legitimate reasons by citizens of countries where the authorities do not have a strong reputation for low and stable inflation, or are held for illegitimate reasons, both at home and abroad.

At the beginning of May 2009, the stock of euro currency notes and coin in circulation amounted to €781bn\(^{10}\). The population of the Eurozone is just under 310 million. This would mean that, if all euro notes were held inside the Eurozone, each man, woman and child would hold just over €2519 in cash. At the end of March 2009, the stock of US$ currency notes and coins outstanding amounted to just under US$904bn.\(^{11}\) With a U.S. population of around 306 million, this means that, if all US$ currency notes were held inside the U.S., per capita U.S. dollar holdings would be US$2950.

The U.S. Treasury (2006) estimated that in 2005 about 50 percent of the stock of U.S. currency was held abroad (see also Rogoff, 1998, 2002). Feige, Faulend, Šonje, and Šošić (2002) report estimates that between 30 and 69 percent of DM currency used to circulate outside the borders of Germany in the final years before the introduction of euro notes in 2002. It is unlikely that the share of euro notes held outside the euro area is significantly lower than the share of DMs held outside Germany towards the end of the DM’s existence.\(^{12}\)

Even assuming 50 percent (in value) of U.S. dollar notes and euro notes are held abroad, it is clear that the distribution of the remaining domestically held notes is likely to be strongly skewed to the right: a small number of persons hold the vast majority of currency by value. The data show that the vast majority of euro and US$ currency (by value) is held in the largest denominations. At the end of March 2009, fully 75 percent of U.S. dollar currency was held in 100 dollar bills—the largest denomination still issued.\(^{13}\) In April 2009, 36 percent of euro notes was held in €500 notes. The €500, €200 and €100 denominations made up 59 percent of the stock of euro notes. The true retail notes, €5, €10 and €20 just accounted for 10 percent of the total value of euro notes.\(^{14}\)

---

\(^{12}\) It is true that the euro is the domestic currency of 15 countries whose inhabitants could have held the DM as a foreign currency before the creation of the euro in 1999 (as well as of Germany). This would tend, cet. par., to make for a lower share of euro currency held outside the 16-country euro area than the share of DM currency held outside Germany, which is just one of the 16 euro area countries. Against this, the euro is already a more important official reserve currency than the DM ever was, and regional and global developments since 1999 have probably increased the demand for a safe and secure foreign currency alternative to domestic currency in many emerging markets.

The only domestic beneficiaries from the existence of anonymity-providing currency are the underground economy—the criminal community, that is, those engaged in tax evasion, money laundering and the financing of terrorism, and those wishing to store the proceeds from crime and the means to commit further crimes out of sight and reach of the authorities. The existence of fiat currency with legal tender status—an anonymity-providing secure store of value provided by the government—represents a subsidy to criminal (illegal/underground) activity. It is particularly surprising to find so many large denomination bank notes, because these are unlikely to be held by poor and low-income households. The usefulness of currency as a means of payment and store of value for low income households is a standard argument in defence of the continued existence of currency in financially developed societies.

Advanced industrial countries can move to electronic and bank-account-based means of payment and media of exchange without any significant transitional problems, permanent efficiency loss or adverse distributional implications. Negative interest rates on bank accounts and on balances outstanding on ‘centralised or networked electronic media’ like credit cards are as easy to implement as positive interest rates. Debit cards simply transfer money between two accounts, both of which could pay negative or positive interest rates without any problems. You could even retain a measure of anonymity and have ‘cash-on-a-chip cards’, which, whenever the balance on the card is replenished by drawing funds from some account, calculate the average balance held on the cash card since the last replenishment and arrange for the appropriate interest rate (positive or negative) to be applied.

Because currency is a redundant or dominated medium of exchange/means of payment for legitimate transactions, except possibly for the smallest denominations, which may still be useful for small retail transactions (up to perhaps €20 or US$20, say), what accounts for its continuing existence and popularity? The only rational argument I can see is that seigniorage, the resources that can be appropriated through the issuance of non-interest-bearing legal tender, is a valuable source of revenue, for the Central Bank or for its beneficial owner, typically the ministry of finance or Treasury. During the year 2007, the Eurosystem earned €49bn as seigniorage from the issuance of bank notes, and during 2008 as much as €86bn.\footnote{Source: ECB, http://www.ecb.int/stats/euro/circulation/html/index.en.html.} From the first week of June 2007 till the first week of June 2008, U.S. currency in circulation increased by US$10.5bn. Between the first week of June 2008 and the first week of June 2009, U.S. currency in circulation increased by US$85.5bn.\footnote{Source: Financial Management Service, http://www.fms.treas.gov/bulletin/}

Is it likely that the social benefits from this seigniorage revenue, together with the convenience benefits that currency still may yield when used in legitimate small retail transactions and held in small savings balances, exceed the social costs of the incremental tax evasion, money laundering, terrorism and other criminality encouraged by the anonymity and privacy provided by currency?

Were fiat currency to be abolished, the loss of any retail transactions benefits could be compensated for by offering free accounts with the Central Bank to all legal residents. These accounts could be administered through commercial banks, post offices and other retail facilities. These accounts, being registered instruments, could, of course, pay a positive, zero or negative rate of interest, as required.

Were the government to decide to abolish government base money, it is possible that the private sector would start supplying a close functional substitute, as it did before such practices were made illegal and the government established its monopoly of currency issuance. If there were no enforceable legal prohibition against this private issuance, it would lead to the case discussed in Section 4.4 below.

By abolishing currency and introducing a close substitute on which interest, positive or negative can be paid, the authorities can remove the lower bound on the short nominal interest rate simply by adopting a rule for the nominal interest rate on money like the one given in Eq. (41). Note that if the policy-determined wedge between the two interest rates were zero, \( \omega = 0 \), Friedman’s optimal quantity of money (OQM) rule would be automatically implemented all the time (\textit{Friedman, 1969}).

\[
\begin{align*}
\bar{i}^M &= i - \omega \\
\omega &\geq 0
\end{align*}
\]
3.2. Taxing currency

As discussed in the Introduction, paying interest, positive or negative requires individual notes (or even coins) to be identifiable as current on any interest due. With the identity of the currency holder unknown to the issuer of the currency, it must be possible to identify the individual notes and coins as being up-to-date on interest due or owed. When interest is received or paid the notes must be marked somehow. Historical proposals for achieving this often involved stamping currency. Silvio Gesell (1916) is an early example of such a proposal, which was also supported by Irving Fisher (1933). In the case of conventional bearer bonds, coupons were physically clipped from the bond document or certificate.

Another variant is to give the currency note an expiration date. Unless this scrip money is stamped no later than the expiration date, it loses its legal tender status. When it is stamped, the negative interest can be collected by the issuer or his agent. Unstamped currency ceases to be recognised as money by the authorities and will thus, in the eyes of the proponents of scrip money, become worthless.

The reason this proposal is incomplete is that the value of fiat money is what people believe it to be; a fiat money note or coin is worth whatever people are willing to exchange it for. No doubt losing legal tender status might undermine people’s confidence in a currency, but many financial instruments have served as means of payment, medium of exchange and store of value without having legal tender status. If enough private agents were to consider a €10 note that had expired (had not been stamped) to be worth as much as a €10 note that was current on interest (had been stamped), then the stamped and unstamped notes would indeed have the same value (exchange for the same bundles of goods and services and for each other).

So to ensure that expired (unstamped) currency does not continue to circulate on a par with current (stamped) currency, a penalty must be imposed on those caught holding or accepting payment in expired (unstamped) currency. The penalty must be sufficient to induce those holding the currency to pay the currency tax. Confiscation of the expired (unstamped) notes, or a fine would be possible enforcement mechanisms of a negative interest rate on currency. This would involve administrative costs and rather intrusive policing, possibly with random spot checks and searches etc. Such monitoring and enforcement of negative interest rates (taxes) on currency would be a rather illiberal policy and unlikely to be popular.

An operational proposal for taxing currency mentioned by Mankiw (2009), who attributes it to one of his graduate students, appears to get around this monitoring and enforcement problem. All currency notes have a serial number ending in an integer from 0 to 9. All currency notes also should have a year printed on them (most I know of do). Once a year, on a fixed date, the Central Bank randomly selects an integer from 0 to 9. All currency notes ending in that integer, printed in that year or earlier, lose their legal tender status and are no longer redeemable/exchangeable at the Central Bank or its agents for anything else.

The expected nominal interest rate on currency is therefore – 10 percent under this scheme, which is effectively a negative interest rate version of the British Premium Bond – a government bond that bears no interest or capital gains but enters the holder into lotteries, based on the serial number of the bond. It can also be viewed as a lottery or randomised version of putting an expiration date on all currency notes and charging a 10 percent of face value tax on each note.

However, the Mankiw scheme falls foul of the same problem that currency with an expiration date falls foul of, unless there is external enforcement. The value of fiat money is what people think it is. If the Central Bank randomly selects 7 as the unlucky number this year and I own a €100 note whose serial number ends in 7, I may still be able to purchase goods and services worth €100 with that note, provided other private agents are willing to accept it as being worth that much. Legal tender status or convertibility into other government notes at the Central Bank are not necessary for fiat money to have value. Some form of monitoring currency holdings and a penalty for those caught with expired currency (such as the threat of confiscation plus a fine) are likely to be necessary to make Mankiw’s scheme work.

If the authorities are willing to incur the administrative and surveillance costs, and to incur the political unpopularity likely to be associated with taxing currency, they could eliminate the lower bound on the risk-free one-period nominal interest rate on non-monetary assets, by adopting a rule
for the one-period own rate of interest on currency (the tax rate on currency) like the one specified in Eq. (41).

3.3. Unbundling the numéraire and the medium of exchange/means of payment

A third way to eliminate the lower bound on the short nominal interest rate was suggested by Eisler (1933) (see also Einaudi, 1953; Gaitskell, 1969). It involves decoupling the numéraire function from the currency, which would retain its means of payment/medium of exchange roles. A simple way to implement this decoupling, which involves the abolition of the old government-issued fiat currency and its replacement by a new government-issued fiat currency is discussed first. Many interesting variations on this theme exist, however, and I shall introduce some of these later in Section 5.

The first step is to abolish the euro currency, by withdrawing all euro notes and coins. The next step is the introduction of a new currency, which I shall call the wim (in honour of Wim Duisenberg, the first President of the European Central Bank). The euro is kept as the numéraire for wage and price contracts. This is an assumption that leads to an interesting model only if it is plausible and will be discussed below.

I believe that there are many ways in which, despite the abolition of physical euro currency, the authorities can encourage the continued use of the euro as numéraire. The government could require all contracts involving the state to be denominated in euro. It could present tax claims and require tax returns in euro, and it could insist on tax payments using euro-denominated instruments. Going beyond that, it could ban bank deposits denominated in wim. As a last resort it could declare all wim-denominated contracts not to be enforceable in Euro Area courts. These and similar measures would make the euro a natural focal point as the choice of numéraire in private contracts.

In the model, private agents and the authorities are free to issue and hold contingent claims denominated in both wim and euro. Specifically, there are both safe one-period wim-denominated bonds and safe one-period euro-denominated bonds.

As there is no longer any euro currency, there no longer is a lower bound on euro interest rates. There is a lower bound on wim interest rates, because there is wim currency. The government sets the sequence of spot exchange rates, or of spot and forward exchange rates, between the euro and the wim.

3.3.1. The private sector in the wim currency economy

The household optimisation problem changes slightly. There is no need here to distinguish between currency and commercial bank deposits with the central bank, so I will omit the latter. Let \( M_t^* \geq 0 \) be the nominal stock of wim currency at the end of period \( t \), \( S_t \) the period \( t \) spot exchange rate between the euro and the wim (number of wim per euro), \( F_{t+1,t}^* \) the one-period forward exchange rate between the euro and the wim (number of wim per euro), \( i_{t+1,t}^* \) the one-period safe nominal interest rate on wim-denominated bonds, \( i_{t+1,t}^{M^*} \) the one-period own rate of interest on wim currency, \( I_{t+1,t}^* \) the nominal wim stochastic discount factor between periods \( t_1 \) and \( t_0 \), \( R_{t_1,t_0}^* \) the real wim stochastic discount factor between periods \( t_1 \) and \( t_0 \), \( P^* \) the wim general price level, \( \Pi_{t_1,t_0} \equiv P_{t_1}^*/P_{t_0}^* \) the wim inflation factor (1 plus the period wim inflation rate to the power \( t_1 - t_0 \)) and \( \Sigma_{t_1,t_0} = S_{t_1}/S_{t_0} \) the wim exchange rate depreciation factor between periods \( t_1 \) and \( t_0 \).

If there is to be no pure (risk-free) arbitrage possibility in this economy, the “law of one price” will have to hold, that is the wim price of goods is the euro price of goods times the wim-euro exchange rate:

\[
P_t^* = S_t P_t
\]

This implies

\[
\Pi_{t_1,t_0} = \Pi_{t_1,t_0} \Sigma_{t_1,t_0}
\]
Also note that:

\[ \frac{1}{1 + r^*_{t+1,t}} = E_t l^*_{t+1,t} \]

and

\[ \frac{1}{1 + r^*_{t+1,t}} = E_t R^*_{t+1,t} \]

Beginning-of-period nominal financial wealth (measured in wim) in period \( t \) is denoted \( W^*_t \). The wim value in period \( t \) (including interest or other income paid) of the portfolio of financial assets other than money purchased in period \( t - 1 \) is denoted \( A^*_t \). These financial aggregates are related as follows:

\[ W^*_t = A^*_t + (1 + i^*_{t+1,t})M^*_t \]

The household's optimisation problem in the wim currency economy becomes

\[ U_0 = E_0 \sum_{t=0}^\infty \beta^t \left[ \frac{1}{1 - \gamma} c_t^{1-\gamma} + \eta \frac{1}{1 - \gamma} \left( \frac{M^*_t}{S_t P_t} \right)^{1-\gamma} \right] \]

(43)

\[ E_t l^*_{t+1,t}W^*_t = W^*_t + S_t P_t (y_t - c_t) - \left( \frac{i^*_{t+1,t} - i^*_{t+1,t}}{1 + i^*_{t+1,t}} \right) M^*_t \]

(44)

\[ E_0 \lim_{t \to \infty} l^*_{t+1,t}W^*_t \geq 0 \]

(45)

\[ M^*_{-1} = \bar{M}^*_{-1} > 0 \]

(46)

\[ A^*_0 = \bar{A}^*_0 \]

(47)

The optimality conditions of this optimisation problem imply the following relations hold:

\[ c_t^{\gamma - 1} = \beta(1 + r^*_{t+1,t})E_t c_t^{\gamma - 1} \]

(48)

\[ \frac{M^*_t}{S_t P_t} = \left[ \eta \left( \frac{1 + i^*_{t+1,t}}{1 + i^*_{t+1,t}} \right) \right]^{1/\gamma} c_t. \]

(49)

\[ 1 + i^*_{t+1,t} = \frac{S_t}{P_t} (1 + i^*_{t+1,t}) \]

(50)

\[ 1 + r^*_{t+1,t} = 1 + r^*_{t+1,t} \]

(51)

\[ \frac{1 + i^*_{t+1,t}}{1 + r^*_{t+1,t}} = E_t \left( \Sigma^{-1}_{t+1,t} + \frac{Cov_t \left( c^{-1}_{t+1,t} \Pi^{-1}_{t+1,t} \right)}{E_t \left( c^{-1}_{t+1,t} \Pi^{-1}_{t+1,t} \right)} \right). \]

(52)

\[ \lim_{t \to \infty} E_t \left( \frac{\beta^T}{c^{\gamma - 1}_{t+1,t} P_t} \right) = 0 \]

(53)

\[ 1 + r^*_{t+1,t} = \left( 1 + i^*_{t+1,t} \right) \left( E_t \Pi^{-1}_{t+1,t} + \frac{Cov_t \left( \Pi^{-1}_{t+1,t} c^{-1}_{t+1,t} \right)}{E_t c^{-1}_{t+1,t}} \right) \]

(54)

In the wim currency economy, the real interest rate on euro bonds is the same as the real interest rate on wim bonds (Eq. (52)). This does not mean, of course, that the wim currency economy behaves identically to the euro currency economy. Although the real interest rate on euro bonds is the same as the real interest rate on wim bonds in the wim currency economy, this common real interest rate can be different from the real interest rate that would prevail in the euro currency economy (starting from the same initial conditions) if there is any probability that the lower bound constraint on the short nominal interest rate would become binding in the euro currency economy.
From the money demand function (50), it is clear that there is a lower bound on the one-period wim nominal interest rate:

\[ i^* \geq i^{M*} \]  

(56)

but since there is no euro currency in the wim currency economy, there is no lower bound on the one-period euro nominal interest rate, \( i \).

Unsurprisingly, covered interest parity (CIP) holds in this economy between euro interest rates and wim interest rates (Eq.(51)). From Eq. (53), uncovered interest parity (UIP) holds only if the risk-premium on euro interest rates, \( Cov_t(c^{-1}_t, \Pi^{-1}_{t+1,t}, \Sigma^{-1}_{t+1,t})/E_t(c^{-1}_t, \Pi^{-1}_{t+1,t}) \), is zero.\(^{17}\) In that case, the euro interest rate (approximately) equals the wim interest rate plus the expected proportional rate of appreciation of the wim in terms of the euro, \( E_t(\Sigma^{-1}_{t+1,t}) - 1 \).

Since the euro remains, by assumption, the numéraire and invoicing currency for wage and price transactions, the Phillips curve is unchanged in the wim currency economy from what it is in the euro currency economy (Eqs. (17) and (18)).

3.3.2. The government in the wim currency economy

The authorities spend and tax as before. They issue wim currency and both wim and euro one-period bonds. Their period budget identity is given in (57) and their solvency constraint in (58).

\[
\frac{M^*_t}{S_t} + \frac{B^*_t}{S_t} = \left(1 + i^{M*}_{t,t-1}\right) \frac{M^*_{t-1}}{S_t} + (1 + \bar{i}_{t,t-1})B_{t-1} + (1 + \bar{i}^*_t \frac{B^*_{t-1}}{S_t}) + P_t(g_t - \tau_t) \tag{57}
\]

\[
E_0 \lim_{t \to \infty} I_{t+1,0} \left[(1 + i^*_{t+1,t})B_t + (1 + \bar{i}^*_t \frac{B^*_{t-1}}{S_t}) \right] \leq 0. \tag{58}
\]

For concreteness assume the government applies the same rule for its lump-sum taxes it used in the euro currency economy, that is,

\[
\tau_t = g_t - \frac{1}{S^*_t} \left(M^*_t - (1 + i^{M*}_{t,t-1})M^*_{t-1} - (1 + \bar{i}^*_{t,t-1})B^*_{t-1} - S_t(1 + \bar{i}_{t,t-1})B_{t-1}\right) \quad t \geq 0 \tag{59}
\]

The Taylor rule for the euro nominal interest rate in the wim currency economy looks as follows:

\[
1 + \bar{i}^*_{t+1,t} = \beta^{-1} \hat{F} + \phi (E_t \Pi_{t+1,t} - \hat{F}) \tag{60}
\]

To complete the policy regime (assuming exogenous real public spending as before), I assign a simple quantitative easing rule for wim currency, when the lower bound constraint in the wim nominal interest rate binds:

\[
\text{If } \bar{i}^*_{t+1,t} = i^{M*}_{t+1,t} \text{ then } M^*_{t+1} = (1 + \mu^*_{t+1,t})M^*_t \tag{61}
\]

where \( \mu^*_{t+1,t} > -1; \ t \geq 0 \) is, for simplicity, an exogenous sequence of proportional growth rates of the nominal stock of wim currency.

Comparing (60) with the Taylor rule for the euro nominal interest rate in the euro currency economy, (24), we note that, because the lower bound constraint on the euro nominal interest rate has been removed, the interest rate now does not switch from the Taylor rule to the quantitative easing rule given by the second line of Eq. (24) and by Eq. (25).

In the wim currency economy, we can represent the monetary authority as having four potential instruments in any given period, \( t \): the short nominal euro interest rate, \( i_{t+1,t} \), the one-period wim nominal interest rate, \( i^*_{t+1,t} \), the spot exchange rate between the euro and the wim, \( S_t \) and the one-period forward exchange rate between the euro and the wim, \( F_{t+1,t} \). The interest rate on wim currency, \( i^*_{t+1,t} \), is, by assumption, not an instrument. All we need is for it to be exogenous. In practice, it is equal to zero. When the lower bound constraint on the short nominal wim interest rate binds, \( i^*_{t+1,t} = \bar{i}^*_{t+1,t} \), the proportional rate of growth of the stock of wim currency, \( \mu^*_{t+1,t} \) becomes an instrument (quantitative easing).

\(^{17}\) Under UIP, \( F_{t+1,t} = (E_t(1/S_{t+1}))^{-1} \).
3.3.3. Equilibrium

Goods market equilibrium in the wim currency economy is given by the same Eq. (27) as in the euro currency economy. The asset market equilibrium condition, however, changes from Eq. (28) to

\[ A^*_t = (1 + i_{t,t-1})S^*_tB^*_t (1 + i^*_t, t-1)B^*_t \]  

(62)

93

3.3.4. How monetary policy is implemented in the wim currency economy

With \( i_{t+1,t}, i^*_t, S_t, \) and \( F_{t+1,t}^* \) as the potential monetary instruments in any period \( t \) and with covered interest parity (Eq. (51)) constraining the four instruments, only three of the four can be chosen independently. In the model under consideration, the short nominal euro interest rate is determined by the Taylor rule (60), regardless of whether this takes the euro nominal interest rate into negative territory. There are infinitely many combinations of rules for the spot and forward exchange rates and the wim rate of interest that are consistent with equilibrium. Any given equilibrium sequence for the real variables and for euro nominal interest rates and euro inflation rates can also be supported by infinitely many different combinations of spot and forward exchange rates and wim rates of interest. I will start by considering a simple, transparent example.

The rule for the one-period risk-free wim nominal interest rate on non-monetary securities satisfies (63), that is, when the euro nominal interest rate set by the Taylor rule (or any other rule) exceeds the lower bound on the wim nominal interest rate, the authorities set the wim interest rate at the same value as the euro interest rate. When the euro nominal interest rate (as determined by the Taylor rule) is equal to or less than the lower bound on the wim nominal interest rate, the authorities set the wim nominal interest rate equal to its lower bound, \( i^{M*} \). This ensures that the lower bound on the wim nominal interest rate, (56), is never violated.

\[ i^{*}_{t+1,t} = i_{t+1,t} if i_{t+1,t} > i^{M*}_{t+1,t} \]

\[ = i^{M*}_{t+1,t}, if i_{t+1,t} \leq i^{M*}_{t+1,t} \]

(63)

From the covered interest parity condition, we know that \( F_{t+1,t}/S_t = (1 + i^*_t, t-1)/(1 + i_{t+1,t}) \), so under the rule given by (63),

\[ F_{t+1,t}/S_t = 1 \] if \( i_{t+1,t} > i^{M*}_{t+1,t} \)

\[ F_{t+1,t}/S_t = 1 + i^{M*}_{t+1,t} \]

\[ 1 + i_{t+1,t} \] if \( i_{t+1,t} \leq i^{M*}_{t+1,t} \)

(64)

With \( i_{t+1,t} \) and \( i^*_t, t+1 \), as instruments (subject to \( i^*_t, t+1 \geq i^{M*}_{t+1,t} \)), the forward premium on the euro, \( (F_{t+1,t}/S_t) - 1 \), is market-determined by covered interest parity. The authorities can set either the spot or the forward exchange rate, with the remaining one residually determined. An easy rule would be to set the spot rate in period \( t \) equal to the one-period forward rate from the previous period:

\[ S_t = F_{t,t-1} \]

(65)

As long as the lower bound constraint on the wim nominal interest rate is not binding, the spot rate \( S_t \) equals this period’s forward rate, \( F_{t+1,t} \). When the lower bound constraint on the wim nominal interest rate is binding, the euro stands at a proportional forward premium to the wim equal to the difference between the interest rate on wim currency and the interest rate on one-period safe euro bonds. Consider the practically relevant case where the interest rate on wim currency is zero (\( i^{M*}_{t+1,t} = 0 \)). It follows that, if the (zero) lower bound constraint on wim interest rates is binding (\( i^*_t, t+1 = i^{M*}_{t+1,t} = 0 \)), the relationship between the spot and forward exchange rates is given by

\[ F_{t+1,t}/S_t = \frac{1}{1 + i_{t+1,t}} \]

(66)

So if the Taylor rule (60) were to imply a negative value for the short nominal euro rate of interest, \( i_{t+1,t} \), there would be no profitable arbitrage possibilities borrowing at the negative euro rate and lending at the zero wim rate, because the forward premium on the euro equals the wim-euro interest
differential. If there is no currency risk premium – $\text{Cov}(e_{t+1}' P_{t+1}' e_{t}^{-1}, \Sigma_{t+1}' e_t^{-1}) = 0$ – the expected proportional rate of appreciation of the euro vis-à-vis the wim would equal the wim-euro interest differential, that is, UIP holds – $F_{t+1,t} = (E_t(1/S_{t+1}))^{-1}$. If UIP holds when the zero lower bound constraint on wim interest rates is binding, a negative euro nominal interest rate is consistent with portfolio balance provided the expected proportional appreciation rate of the euro vis-à-vis the wim exactly compensates for the negative interest rate on the euro:

$$1 + i_{t+1,t} = 1 + i_{t+1,t} = E_t \left( \frac{S_t}{S_{t+1}} \right)$$

(67)

So if $i_{t+1,t} < 0$, then $E_t \left( \frac{S_t}{S_{t+1}} \right) = 1 + i_{t+1,t} < 1$.

3.3.5. Would the numéraire ‘follow the currency’?

Key to the effectiveness of the unbundling solution is the assumption that the euro remains the numéraire for wage and price contracting, even after the euro currency has been abolished and replaced by the wim currency, that is, that the euro price level Phillips curve (17) remains the operational one and that the inflation rate of concern to the authorities is the proportional rate of increase in the euro general price level, as exemplified in the wim currency model by the continued relevance of the Taylor rule for the euro interest rate (without the lower bound), given in (60).

If the numéraire instead were to ‘follow the currency’ and as a result a wim price level Phillips curve were to replace the euro price level Phillips curve, and a wim short nominal interest rate Taylor rule with a wim target rate of inflation and a lower bound on the wim short nominal interest rate were to replace the euro short nominal interest rate Taylor rule with its euro target inflation rate and its lower bound on the euro short nominal interest rate, then we would have achieved no more than a pure change in the unit of account for the euro currency economy, like the change from old French francs to new French francs in January 1960, with 100 old French francs = 1 new French franc. The zero lower bound would continue to exist in the new French franc economy as it had in the old French franc economy.

Monetary economics has very little to say about what or who determine what the numéraire is or about what physical, fiat or imaginary substances serve as numéraire. Even the great monetary thinkers of previous generations had little to contribute, other than anecdotes or appeals to common sense (see e.g., Hicks, 1967; McCallum, 1989; Niehans, 1978; Patinkin, 1965).

Fundamentally, the set of physical or abstract objects a unit of which defines the (or a) unit of account in an economy is determined through a collective but uncoordinated, decentralised social choice by the agents making up the economy.18 The monetary, fiscal and regulatory authorities can certainly encourage the use of a particular financial instrument as unit of account, as discussion i paragraph 3 of Section 3.3. What does history tell us happened when numéraire and currency parted ways?

The unit of account used most widely in a society need not be the unit of denomination of whatever financial instruments are used as means of payment and medium of exchange. Everyone is familiar with the Guinea, which was neither the official unit of account used by the UK monetary authorities in their transactions, nor a medium of exchange/means of payment after 1813, but continued to be used as the numéraire in auction houses and expensive and pretentious shops until decimalisation in 1971.

The history of primitive monies, described in Paul Einzig’s book (Einzig, 1949) contains many examples of the decoupling of the official numéraire function both from the private numéraire and from

---

18 Careful scholars in the field of monetary economics have long made the point that it makes no sense to say that money serves as a (or the) unit of account, “...since money is a tangible material not a unit of measurement.” (McCallum, 1989, p. 17, fn. 1). Correct usage would be to say “...that the medium of account is the good some quantity of which serves as the unit of account (i.e., is used as the base for quoted prices)” (McCallum, 1989, p. 17, fn. 1). Niehans (1978), p. 118, fn 1 makes the same point: “Money is here called a medium and not, as customary, a unit of account because, clearly, money itself is not a unit, but the good whose unit is used as the unit of account.”
the medium of exchange/means of payment function. Medieval Iceland had a cattle, a cloth and a fish-standard. The monetary unit known as the kugildi was defined precisely in terms of a standardized cow. It is doubtful, for simple logistic reasons, that the kugildi could ever have been extensively used as a medium of exchange. Einzig reports that in documents it was often explicitly stated that “...payment fixed in kugildi was actually to be made in metallic money or in other form” (Einzig, 1949, p. 260). Plain home-woven woollen cloth (wadmal) served as a general standard of value (unit of account) throughout the Icelandic medieval period.

Wadmal was used to determine the amount of wergeld (compensation for wrongful death) to be paid and for the valuation of damages. Taxes were fixed in wadmal. Unlike kugildi, wadmal was widely used as a medium of exchange. There was a fixed legal exchange rate between kugildi and wadmal. In the 15th century, dried stockfish appears to have been used widely in Iceland as a unit of account. Einzig expresses doubt as to whether it was widely used as a medium of exchange (Einzig, 1949, p. 262), and one can only hope he is right in this. In the case of the wadmal, it is interesting that, while the authorities fixed taxes in terms of wadmal, there was no monetary authority with a monopoly of the supply of wadmal. Every home with a spinning wheel and a hand-loom could become a private mint.

In more recent times, and even in the fiat money era, there are examples that support the view that the unit of account used most widely in a society need not be the official monetary unit used to define (some of) the liabilities of the Central Bank. In countries with very high inflation or hyperinflation, the unit of account has often been a more stable foreign currency, although the means of payment/medium of exchange for small-scale retail transactions remained the national currency. For instance, the U.S. dollar played that role in Israel during the inflation surge that prompted the successful stabilisation plan of July 1985 and in Peru during the hyperinflation that led to the successful stabilisation package of August 1990. The U.S. dollar was used as the numéraire for posting retail prices, but after a hasty verification of the current exchange rate, retail transactions tended to be settled in shekels, respectively intis or soles.

An interesting, albeit short-lived monetary experiment took place in the eleven countries that made up the Eurozone between the date of the official designation of the euro as the new numéraire on January 1, 1999 and the introduction of the physical euro currency around January 1, 2002. During that three-year period, the national legacy currencies continued to function as media of exchange and means of payment for retail cash transactions.

Officially, however, the euro was the numéraire from January 1, 1999 on, and the national currencies represented inconvenient non-integer denominations of the euro. In reality, however, the national legacy currencies continued to be used overwhelmingly as the unit of account not just in transactions involving payment with these national legacy currencies, but also in contracts that might be settled using non-cash means of payment. The numéraire in the bulk of private transactions (cash and non-cash) stayed with the means of payment/medium of exchange despite the introduction of the new numéraire, the euro. In practice, until euro currency was introduced and the national legacy currencies lost their legal tender status, the euro was treated as an inconvenient non-integer denomination of the national legacy currencies.

All three methods for eliminating the lower bound on nominal interest rate make it possible to target true price stability (\(\hat{\Pi} = 1\)) or any low rate of inflation without fear of hitting the lower bound. The inflation targets of most real-world Central Banks, including the ECB (close to but below 2 percent per annum for the HICP), the Bank of England (2 percent per annum for the CPI) and the Fed (an informal target for core CPI inflation of between 1.5 and 2.0 percent per annum) are for positive rates of inflation rather than for a zero rate of inflation for two reasons. The first is that there are biases in the price indices used to measure inflation that cause the measured rate of inflation to overstate the true rate of increase in the cost of living. The second is that the asymmetry in the policy maker’s choice set created by the zero lower bound on nominal interest rates makes it desirable to target an inflation rate somewhat higher than the one that would be targeted without the existence of the zero lower bound. This second argument for targeting a positive rather than a zero rate of inflation would no longer apply.

19 Greece became the 12th Euro Area member on January 1, 2001.
Both taxing currency and unbundling numéraire and currency would permit the authorities to implement Friedman’s optimal quantity of money (OQM) rule without this constraining the rate of inflation that is targeted.

When currency is taxed, the tax rate is $-iM$. The OQM rule, which requires a zero pecuniary opportunity cost of holding base money, that is, $i = iM$, still leaves the nominal interest rate free to target any rate of inflation. In terms of Eq. (41), we set $\omega$, the wedge between the nominal bond interest rate and the nominal interest rate on currency, equal to zero.

When numéraire and currency are decoupled, the OQM is satisfied with the wim rate of interest, $\tilde{t}^*$ equal to the (exogenous) rate of interest on wim currency, $t^M$ (which could be zero without affecting the argument). Clearly, this pins down the rate of inflation in terms of wim, $\beta^{-1}$. In the deterministic flexible price version of the model with constant values of the exogenous variables, the stationary fundamental solution would have the wim inflation rate equal to minus the real interest rate: $\tilde{\pi}^* = \left(\frac{1}{1+r^*}\right) = \left(\frac{1}{1+r}\right)^{-1}$. However, the euro rate of inflation can be anything the authorities want it to be, because the euro nominal interest rate can be set freely: $\tilde{\pi} = \beta(1 + i)$.

4. Alternative implementations and interpretations of the unbundling of numéraire and currency

4.1. Retaining the old currency but no longer supplying it on demand at a fixed parity with bank reserves at the Central Bank

This is no more than a re-interpretation of the wim currency economy. It interprets the wim currency model as a real-time evolution of the euro currency model, modified with the assumption that the authorities no longer exchange one euro worth of euro currency notes (at face value) for one euro worth of euro-denominated one-period bonds (at face value) when they wish to set the interest rate on euro-denominated bonds at a zero or negative value. The ‘currency euro’ is different from the ‘non-monetary euro’.

More precisely, in the euro currency economy, let the monetary base consist of currency and bank reserves with the Central Bank: $M = N + D$. Assume that the interest rate on euro currency is zero and that the interest rate on euro reserves held with the Central Bank is the one-period nominal euro bond rate: $i^N = 0$ and $i^D = i$. Assume for simplicity that only euro currency appears in the direct utility function: $U_0 = E_0 \sum_{t=0}^{\infty} \beta^t \left[ \frac{1}{1 - \gamma} c_{t+1}^{1-\gamma} + \eta(1/1 - \gamma) \ln \left( \frac{N_t}{P_t} \right) \right]$. Bank reserves are perfect substitutes for one-period euro bonds. As long as the zero lower bound on the euro nominal interest rate is not binding, the authorities supply euro currency on demand at a fixed exchange rate with euro bonds: $S_t = S_{t+1} = F_{t+1,t}$ as long as $i > 0$. Starting from a position like the present, when negative nominal interest rates have not occurred in the past, the natural value of this constant exchange rate would be 1. Note that in this interpretation it is the euro bond that is the numéraire in terms of which prices and wages are set, not the euro currency.

If in period $t$ the zero lower bound on the euro nominal interest rate becomes a binding constraint, I assume, for simplicity, that the authorities set the period $t$ spot exchange rate $S_t$ at the same value as the period $t - 1$ forward rate, that is, $S_t = F_{t, t-1}$ (which would equal 1 in the current historical episode), but the period $t$ forward rate will now be set at the level required to produce that value of the forward premium for the euro bond vis-à-vis the euro currency that prevents arbitrage between euro bonds and euro currency.

In general, the authorities would set the interest rate on euro bonds and the spot and forward exchange rates between euro bonds and euro currency to satisfy:

$$\frac{F_{t+1,t}}{S_t} = 1 \quad \text{if} \quad i_{t+1,t} > 0$$

$$\frac{F_{t+1,t}}{S_t} = \frac{1}{1 + i_{t+1,t}} \quad \text{if} \quad i_{t+1,t} \leq 0$$

(68)
Note that since the spot exchange rate is a policy instrument, we do not have to worry about appropriate boundary conditions to pin down the initial value of the exchange rate. This can be given by history (at 1 today) or by government fiat.

4.2. A floating exchange rate version of the euro bond and euro currency model

The issue of an appropriate boundary condition (that is, terminal or initial condition) for the spot exchange rate must be addressed in the floating exchange rate version of the model considered in the previous subsection.

Instead of viewing the exchange rate of the euro bond vis-à-vis the euro currency as the instrument and the stock of euro currency as endogenously determined (or demand-determined), we can have the authorities select some trajectory (or rule) for the nominal stock of euro currency whenever they wish to set a negative interest rate for euro bonds. The QE rule(25) would become

\[ \text{If } i_{t+1,t} \leq i^M_{t+1,t} \text{ then } M_{t+1} = (1 + \mu_{t+1,t})M_t \]

The exchange rate of euro bonds vis-à-vis euro currency could then be determined by a competitive market process.

I continue to assume that the interest rate on euro bonds is determined by the Taylor rule (60). Should the Taylor rule take the nominal interest rate for euro bonds into positive territory, after at least one period of non-positive interest rates, the exchange rate would be fixed again. If period \( t \) is the first period the nominal interest rates on euro bonds becomes positive again after a spell in zero or negative territory, I assume, for simplicity, that \( S_t = F_{t,t-1} \). When the interest rate on euro bonds is positive, the exchange rate between the euro bond and the euro currency is fixed and the euro currency stock is demand-determined.

It is obvious that the exchange rate equations in (68), which were constructed to avoid arbitrage possibilities, will also characterise a competitive market solution for the exchange rate. In this case, however, we need a boundary condition, in the form of a terminal condition, to pin down the initial value of the exchange rate. The reason for this is obvious from the no-arbitrage equilibrium condition (53), which (because the interest rate on currency is zero) allows the exchange rate process(68) to be written as:

\[ F_{t+1,t} = S_t \text{ if } i_{t+1,t} > 0 \]

\[ 1 + i_{t+1,t} = E_t \left( \frac{S_t}{S_{t+1}} \right) + \frac{\text{Cov}_t(c_t^{-1} \Pi_{t+1,t-1}, S_t/S_{t+1})}{E_t(c_t^{-1} \Pi_{t+1,t-1})} \text{ if } i_{t+1,t} \leq 0 \]  

(69)

This shows that the current spot exchange rate depends on the entire future (stochastic) path of euro interest rates and risk-premia, and on a terminal boundary condition or initial condition for this stochastic exchange rate process. As there is no easy intuitive way to specify a terminal boundary condition for the spot exchange rate, I finesse the problem by assuming that the authorities set (fix) the initial value of the spot exchange rate during any period when the euro bond interest rate becomes zero or negative, if in the previous period it was positive. All subsequent exchange rates are market-determined. Concretely, I assumed that the authorities set the initial value of the spot exchange rate in that period at the value of the one-period forward exchange rate from the previous period. So the exchange rate satisfies (as in the managed exchange rate regime of the previous subsection):

\[ S_{t+1} = F_{t+1,t} = S_t \text{ if } i_{t+1,t} > 0 \]

\[ \frac{F_{t+1,t}}{S_t} = \frac{1}{1 + i_{t+1,t}} \text{ if } i_{t+1,t} \leq 0 \]

\[ 1 + i_{t+1,t} = E_t \left( \frac{S_t}{S_{t+1}} \right) + \frac{\text{Cov}_t(c_t^{-1} \Pi_{t+1,t-1}, S_t/S_{t+1})}{E_t(c_t^{-1} \Pi_{t+1,t-1})} \text{ if } i_{t+1,t} \leq 0 \]  

\( S_t = F_{t,t-1} \) if \( i_{t+1,t} \leq 0 \) but \( i_{t,t-1} > 0 \)  

(70)
4.3. A floating exchange rate version of the wim currency model with ‘pet rocks’

There is nothing in the logic of the model that requires the fiat currency to be provided by the government. Assume that instead of fiat paper or electronic currency, there is some exogenous supply of intrinsically worthless objects, say ‘pet rocks’ like rai, the stone money of the Yap islands. These are large, doughnut-shaped carved disks, usually of calcite, that can be up to 4 meters in diameter, although most are much smaller. Money would disappear from the government budget constraint (57), which would become

\[ B_t + \frac{B_t^*}{S_t} = (1 + i_{t,t-1} B_{t-1} + (1 + i_{t,t-1}^* B_{t-1}^*) + P_t (g_t - \tau_t) \]

and from the government tax rule (59), which would become \( \tau_t = g_t - (1/SP_t)((1 + i_{t,t-1}^* B_{t-1}^* - S_t(1 + i_{t,t-1} B_{t-1})). \) The government solvency constraint (58) would be unaffected. Note that the pet rock money is a true ‘outside asset’, an asset to the owner but not a liability of anyone else—‘nature’ was the issuer.

As long as there is an exhaustive initial assignment of property rights for the pet rocks, the household optimisation problem would not be affected. The own rate of interest on this pet rock currency is zero. In the case of rai, the total stock is given, but in principle the supply could change exogenously over time (if meteorites were the currency, say) as long as any addition to the stock has an exhaustive assignment of property rights today.

In the pet rock currency model, pinning down the initial value of the exchange rate between one unit of euro bonds and a unit of pet rocks, during a period when the interest rate on euro bonds goes negative after being positive in the previous period, would again require either a terminal boundary condition, or an initial condition for the exchange rate. In the case of fiat euro currency, the authorities certainly have the ability to set the value of the exchange rate in any period, as they can issue any (non-negative) amount of currency. This is not true in the case of pet rocks whose aggregate supply is given and finite. All I can offer at this point is that the solution for the stochastic exchange rate path given in (70) is a solution for the case where currency consists of pet rocks. There are bound to be many other solutions as well, however.

4.4. A private currency interpretation of the model

Assume that, in the euro currency economy, the government abolishes its fiat currency and retires all notes and coin. Assume that the prohibition against the private issuance of currency were lifted. Assume that there are private firms (banks) owned by the households. These then create/produce non-interest-bearing currency, again called ‘wim’ for the representative bank. Assume the banks maximise profits and that there is free entry and exit into the banking sector. In equilibrium the banking sector will therefore make no pure profits, so we do not have to worry about including bank equity in the asset menus and endowments of the households. If euro bonds and euro base money on which interest can be paid (bank reserves with the Central Bank) are imperfect substitutes for the old euro currency but the new private currency is a perfect substitute for the old euro currency, the real demand for the new private currency would still be given by Eq. (50).

When writing down the profit function of a bank, we must make an assumption about whether the currency it issues is irredeemable in the sense we assumed government fiat money to be irredeemable. If it is irredeemable, the present discounted value of the terminal stock of private bank currency outstanding can be positive, if not, it must be zero. For private banks I prefer the assumption that the currency they issue must ultimately be redeemed in present discounted value terms. Let \( f_t \) be the fixed real cost of producing currency in period \( t \). The representative bank maximizes the present discounted value of current and future real profits:

\[ E_t \sum_{j=1}^{\infty} R_{t+j,t}^e \left( \frac{\Delta M_{t+j}^e}{P_{t+j} - f_{t+j-1}} \right) \]
I have assumed the marginal cost of issuing currency is zero (a reasonable assumption, as it is always possible, with negligible cost, to add a zero to the face value of a currency note). In that case, there will be an incentive in each period, in a competitive setting where each bank takes the general price level, \( P^* = SP \), and the stochastic discount factors \( R^*_t+j \) as given, to continue issuing currency, that is, to boost \( \Delta M^*_t \), as long as currency has any positive value. An infinite price level in each period would be the outcome—there would be no equilibrium in which money has positive value.

If there were a private monopoly, which allowed for the endogeneity of discount rates and prices, the present discounted value of current and future real seigniorage would, for money demand functions that have the Laffer curve property (see Buiter, 2007b) be maximised (in the stationary case), when the wim risk-free nominal interest rate equals the reciprocal of the (absolute value of the) semi-elasticity of demand for money with respect to that interest rate. Since this is surely a positive number, the zero lower bound would never bind in this economy. The budget constraints of the households would have to be modified to include their share of the profits from the monopoly bank.

If the private sector were regulated (neither competitive nor a monopoly), the authorities could restrict the rate of issuance of private wim currency to the point that the zero lower bound on wim interest rates became a binding constraint. In that case, we would, except for the distribution of the profits of the regulated banking sector, be back to the case of the wim currency model with pet rocks.

5. The liquidity trap and quantitative easing

The model has implications for the conditions under which a liquidity trap exists in the case where the lower bound constraint is not removed by applying any of the three methods outlined in Sections 3 and 4. I interpret a liquidity trap as an equilibrium in which risk-free nominal interest rates at all maturities are at their lower bound (typically zero). There are stronger versions of the liquidity trap, which require not only that risk-free nominal interest rates at all maturities be at their lower bounds, but also that all liquidity premia at all maturities be zero also.

In the model used in this paper, which is a complete markets model with frictionless markets, there are no liquidity premia. Indeed, as the complete markets assumption is combined with the (implicit) assumption that there is costless enforcement of the intertemporal budget constraints of all agents, there are no default risk premia, as every agent, in every state of nature, always satisfies his intertemporal budget constraint and consequently there is no default risk.

It is easily shown in the model of this paper that there exists no liquidity trap equilibrium in this economy, unless the authorities demonetise the economy. In this section I return to the euro currency model of Section 2.

In period \( t \), the risk-free nominal discount factor over a \( j \)-period horizon, \( j \geq 1 \), is defined by

\[
E_t I_{t+j,t} = E_t \prod_{k=t+1}^{t+j} I_{k,k-1}
\]

\[
= E_t \left( I_{t+1,t} E_{t+1} \left( I_{t+2,t+2} E_{t+2} \left( I_{t+3,t+2} \left( ... E_{t+j-1,t+j-1} I_{t+j,t+j-1} \right) \right) \right) \right) = \prod_{k=t+1}^{t+j} \frac{1}{1 + i_{k,k-1}}
\]

In a liquidity trap, therefore, \( i_{k+1,k} = \frac{i_{M}^{*}}{k+1,k} \), \( k \geq t \). Now consider the household solvency constraint (16), which holds with equality, the definition of private financial wealth (7), the asset market equilibrium condition (28) and the government solvency constraint (22). Assume the government solvency constraint holds with equality—this is a policy choice open to the authorities. We then obtain from the household solvency constraint:

\[
\lim_{j \to \infty} E_t I_{j+1,t} \left( (1 + i_{j+1,j}) B_j + (1 + i_{M}^{*} j+1,j) M_j \right) = 0
\]  

(71)

and from the government solvency constraint:

\[
\lim_{j \to \infty} E_t I_{j+1,t} (1 + i_{j+1,j}) B_j = 0
\]  

(72)
Eqs. (71) and (72) imply that,

$$\lim_{j \to \infty} E_t I_{j+1, t}(1 + j_{j+1, t}) M_j = 0 \quad (73)$$

Assume that we are in a liquidity trap equilibrium and that under the QE rule adopted (see Eq. (25)), the growth rate of the nominal money stock is deterministic. It is easily seen that (73) is violated unless the proportional growth rate of the nominal stock of base money is below the interest rate on base money. In a liquidity trap

$$\lim_{j \to \infty} M_j \prod_{k=t+1}^j \left( \frac{1 + \mu_{k, k-1}}{1 + i_{M, k-1}} \right) = 0 \quad (74)$$

This will only be satisfied if the long run expected proportional growth rate of the monetary base is less that the long-run value of $i_{M}$. Consider the practically relevant case where the nominal interest rate on currency is zero. Eq. (74) becomes

$$\lim_{j \to \infty} E_t M_j = \lim_{j \to \infty} M_j \prod_{k=t+1}^j (1 + \mu_{k, k-1}) = 0 \quad (75)$$

So a liquidity trap equilibrium exists only if the authorities are expected to demonetise the economy in the long run.

Eq. (73) is almost the same as the transversality condition of the household optimum problem given in (14), although it is an implication of solvency constraints (that is, of the intertemporal budget constraint which is always satisfied) rather than an optimality condition which is obtained by the household optimizing subject to the intertemporal budget constraint.

Unless the authorities demonetize the economy in the long run (if the interest rate on currency is zero), there can be no liquidity trap equilibrium because the shadow value of the terminal money stock would not go to zero. Households would severally try to get rid of excessive money balances, something that, in the aggregate they cannot do. This can be viewed as a formal version of the ‘hot potato’ view of money.

Friedman’s optimal quantity of money (OQM) equilibrium rule (Friedman, 1969) does indeed have the property that the nominal stock of base money goes to zero asymptotically, even though there is satiation in real money balances in every period (see Buiter and Sibert, 2007).

6. Conclusion

This paper discusses three methods for removing the zero lower bound on nominal interest rates. All three are technically feasible, indeed operationally simple. Abolishing currency may seem drastic, but should present no significant logistical problems for advanced economies, except for the underground (grey and black) economy. Taxing currency would be the most administratively demanding and intrusive of the three methods. Unbundling the numéraire from the currency would seem to have lack of familiarity as the main argument against it.

Whatever the demerits of these three operational schemes for removing the lower bound on nominal interest rates, they must be set against the economic cost of handicapping the Central Bank in its pursuit of expansionary monetary policies through the continued existence of the zero floor. If, but for the zero lower bound, the Federal Funds target rate ought indeed to have been set at minus five percent, the cost of the Fed being unable to set its official policy rate below zero could be serious indeed. We do not know what scale and scope of unconventional monetary policies, such as quantitative easing, credit easing or enhanced credit support, can compensate for the asymmetry in the domain over which the official policy rate can range. It may indeed be the case that no amount of quantitative easing or credit easing can make up for the inability of the monetary authorities to set negative nominal interest rates. The subject matter of this paper is therefore not a theoretical curiosum. It is a practical monetary policy issue of great importance.
